

DNS, Domains, and Subdomains

Explained Like You're 10!

Author: [Zayan Ahmed](#) | Estimated Reading time: 4 mins

Have you ever wondered how you visit your favorite website like www.youtube.com or www.google.com? 🤔

It looks like magic, but it's all thanks to something called **DNS**, **Domains**, and **Subdomains**.

Let's explore these step by step!

DNS
DOMAIN NAME SERVICES

What is a Domain?

A **domain** is like the name of a house on the internet. Just like your home has an address (like *123 Main Street*), websites have names like:

- **google.com**
- **youtube.com**

- **minecraft.net**

These names are called **domains**. They make it easy for people to visit websites without needing to remember a bunch of numbers.

 Remember:

A domain = a website's easy-to-remember name.

What is DNS?

DNS stands for **Domain Name System**.

Let's say you want to visit www.pokemon.com.

Your computer doesn't really understand names like that—it only understands **IP addresses** (which are like phone numbers for computers).

So when you type in a website name, **DNS works like a phone book**. It looks up the domain name and finds the real number (IP address) for that website.

Example:

- You type: www.roblox.com
- DNS finds the number: **128.116.44.2**
- Your computer says, "Aha! Let's go there!"

 **DNS = Name finder that connects you to websites.**

What is a Subdomain?

A **subdomain** is like a room inside the house (the domain).

Let's say you have a big house called **myhouse.com**. Inside it, you can have rooms like:

- **kitchen.myhouse.com**
- **bedroom.myhouse.com**
- **games.myhouse.com**

These are called **subdomains**—they are parts of the main domain and usually serve different purposes.

Example:

- **mail.google.com** → The Gmail inbox 
- **maps.google.com** → Google Maps 
- **docs.google.com** → Google Docs 

 Subdomains help keep websites organized by purpose.

How Do They Work Together?

Let's break it down with a simple story:

 You are Sarah. You want to visit **games.coolkidsclub.com**

1.  Your brain (browser) asks DNS: "Where is *games.coolkidsclub.com*?"
2.  DNS looks it up and says, "Here's the IP address!"
3.  Your computer connects to that address.
4.  You're now on the **games** part of the Cool Kids Club website.

So cool, right?

Real-Life Scenarios

Here are some examples of how domains and subdomains are used in real life:

A School Website:

- **school.com** → The main site
- **homework.school.com** → Homework portal
- **students.school.com** → Student info
- **teachers.school.com** → Teacher portal

An Online Store:

- **shopcoolstuff.com** → Main website
- **blog.shopcoolstuff.com** → Articles and news
- **support.shopcoolstuff.com** → Help and support
- **checkout.shopcoolstuff.com** → Buying stuff

A Game Studio:

- **gameland.com** → Main site
 - **download.gameland.com** → Download page
 - **forum.gameland.com** → Talk with other players
 - **play.gameland.com** → Play the game directly
-

Quick Recap!

Word	What It Means	Easy Example
Domain	Website name	<code>google.com</code> , <code>roblox.com</code>
DNS	Finder that connects names to numbers	Turns <code>google.com</code> into an IP 📞
Subdomain	Part of a main domain, like a room in a house	<code>mail.google.com</code> , <code>play.games.com</code>

Final Thoughts

The internet is full of **names, numbers, and rooms**—and **DNS, Domains, and Subdomains** help keep it all organized.

Now that you know what they are, next time you visit a website, you'll know what's going on behind the scenes!

Loved THAT ! 😬
